INVENTION TITLE:

"Operator carried power tool having a four-cycle engine"

The following statement is a full description of this invention, including the best method of performing it known to us:

OPERATOR CARRIED POWER TOOL HAVING A FOUR-CYCLE ENGINE

5 This invention relates to operator carried power tools and more particularly, to operator carried power tools driven by a small internal combustion engine.

10 Portable operator carried power tools such as line trimmers, blower/vacuums, or chain saws are currently powered by two-cycle internal combustion engines or electric motors. With the growing concern regarding air pollution, there is increasing pressure to reduce the emissions of portable power equipment.

15 Electric motors unfortunately have limited applications due to power availability for corded products and battery life for cordless devices. In instances where weight is not an overriding factor such as lawn mowers, emissions can be dramatically reduced by utilizing

20 heavier four-cycle engines. When it comes to operator carried power tools such as line trimmers, chain saws and blower/vacuums, four-cycle engines pose a very difficult problem. Four-cycle engines tend to be too heavy for a given horsepower output and lubrication

25 becomes a very serious problem since operator carried power tools must be able to run in a very wide range of orientations.

30 The California Resource Board (CARB) in 1990 began to discuss with the industry, particularly the Portable Power Equipment Manufacturer's Association

- 2 -

(PPEMA), the need to reduce emissions. In responding to the CARB initiative, the PPEMA conducted a study to evaluate the magnitude of emissions generated by two-cycle engines in an effort to determine whether they were capable of meeting the 5 proposed preliminary CARB standards tentatively scheduled to go into effect in 1994. The PPEMA study concluded that at the present time, there was no alternative power source to replace the versatile lightweight two-stroke engine currently used in hand held products. Four-cycle engines could only be used in 10 limited situations, such as in portable wheeled products like lawn mowers or generators, where the weight of the engine did not have to be borne by the operator.

According to the present invention, there is provided a 15 portable, operator-carried power tool having a frame and an operator-controlled implement supported by the frame at one end thereof, said tool having a four-cycle internal combustion engine having a displacement not greater than 80cc, being drivably connected to said implement and being attached to said 20 frame.

Further according to the present invention, there is provided a portable operator-carried power tool having a frame to be carried by an operator, an implement co-operating with the 25 frame and having a rotary driven input member and an internal combustion engine attached to the frame provided with an output member operatively coupled to the implement input member the engine including a lightweight engine assembly having portions thereof forming an engine block and a cylinder head assembly, 30 the engine block having defined therein a cylindrical bore, the

cylinder head assembly having defined therein a spark plug hole and having partially defined therein a combustion chamber, the engine further including a crankshaft, a piston and a connecting rod assembly the engine being a four-cycle engine comprising:

5 a cam rotatably driven by the crankshaft, the crankshaft having an axial shaft with an output end adapted to be attached to the implement input member and an input end coupled to a parallel radially offset crankpin and a counterweight;

the engine further having an enclosed oil reservoir which 10 is partially filled with a quantity of oil, and the bearing journal for rotatably supporting the crankshaft;

the cylindrical bore having a substantially upright orientation within the engine block;

the piston reciprocally co-operating within the bore to 15 provide an engine displacement not greater than 80cc;

the connecting rod assembly including a first end having a bearing for pivotally co-operating with the piston and a bearing assembly for pivotally co-operating with the crankshaft;

a splasher driven by the crankshaft to engage the oil 20 within the enclosed oil reservoir in order to create an oil mist which lubricates the engine;

the cylinder head assembly defining a combustion chamber in co-operation with the cylinder bore and the piston, the cylinder head assembly having a spark plug and overhead intake and 25 exhaust ports extending into the combustion chamber with an intake valve and an exhaust valve respectively co-operating therewith; and

a valve train operatively co-operating with the cam for sequentially activating the intake and exhaust valves at one- 30 half engine speed.

- 4 -

Preferred embodiments of the invention seek to enable one or more of the following objectives to be achieved:

to provide a hand held powered tool which is powered by an internal combustion engine having low emissions and is 5 sufficiently light to be carried by an operator;

to provide a portable hand held powered tool powered by a small internal combustion engine having an internal lubrication

33

33

33

system enabling the engine to be run at a wide variety of orientations typically encountered during normal operation;

to provide a portable power tool to be carried by an operator which is driven by a small lightweight four-cycle 5 engine having an aluminum engine block, an overhead valve train and a splasher lubrication system for generating an oil mist to lubricate the crank case throughout the normal range of operating positions;

to provide an oil mist pumping system to pump an oil mist 10 generated in the crank case into the overhead valve chamber.

A portable hand held power tool of a preferred embodiment of the present invention intended to be carried by an operator is provided utilising a small four-cycle internal combustion 15 engine as a power source. The four-cycle engine is mounted on a frame to be carried by an operator during normal use. The tool has an implement cooperating with the frame having a rotary driven input member coupled to the crankshaft of the four-cycle engine. The four-cycle engine is provided with a lightweight 20 aluminum engine block having at least one cylindrical bore oriented in a normally upright orientation having an enclosed oil reservoir located therebelow. A crankshaft is pivotably mounted within the engine block. The enclosed oil reservoir when properly filled, enables the engine to rotate at least 30 25 degrees about the crankshaft axis in either direction without oil within the reservoir rising above the level of the crankshaft counter weight. A splasher is provided to intermittently engage the oil within the oil reservoir to generate a mist to lubricate the engine crank case.

- 5A -

One embodiment of the invention pumps an oil mist from the crank case to an overhead valve chamber to lubricate the valve train.

5 In yet another embodiment of the invention, the overhead valve chamber is sealed and is provided with a lubrication system independent of the crank case splasher system.

Embodiments of the invention will now be described, by way 10 of example only, with reference to the accompanying drawings in which:

Figure 1 is a perspective view illustrating a line trimmer of a preferred embodiment of the present invention;

5 Figure 2 is a cross-sectional side elevation of the engine taken along line 2.2 of Figure 1;

Figure 3 is side cross-sectional elevational view of the engine of Figure 2;

Figure 4 is an enlarged schematic illustration of the cam shaft and the follower mechanism;

Figure 5 is a cross-sectional side elevational view of a second engine embodiment;

Figure 6 is a cross-sectional end view illustrating the valve train of the second engine embodiment of Figure 5;

Figure 7 is a cross-sectional side elevational view of a third engine embodiment;

Figure 8 is an enlarged cross-sectional view of the third engine embodiment of Figure 7 illustrating the lubrication system;

Figure 9 is a partial cross-sectional end view of the third engine embodiment shown in Figure 7 and 8 further illustrating the lubrication system;

Figure 10 is a timing diagonal of the lubrication system of the third engine embodiment;

Figure 11 is a torque versus RPM curve; and

Figure 12 and Figure 13 contrast the pull force of a four and a two-cycle engine.

Figure 1 illustrates a line trimmer 20 made in accordance with the present invention. Line trimmer 20 is used for illustration purposes and it should be appreciated that other hand held power tools tended to be carried by operators such as chain saws or a blower vacuum can be made in a similar fashion. Line trimmer 20 has a frame 22 which is provided by an elongated aluminum tube. Frame 22 has a pair of handles 24 and 26 to be grasped by the operator during normal use. Strap 28 is placed over the shoulder of the user in a conventional manner in order to more conveniently carry the weight of the line trimmer during use. Attached to one end of the frame generally behind the operator is a four-cycle engine 30. The engine drives a conventional flexible shaft which extends through the center of the tubular frame to drive an implement 32 having a rotary cutting head or the like affixed to the opposite end of the frame. It should be appreciated that in the case of a chain saw or a blower/vacuum, the implement would be a cutting chain or a rotary impeller, respectively.

Figure 2 illustrates a cross-sectional end view of a four-cycle engine 30. Four-cycle engine 30 is made up of a lightweight aluminum engine block 32 having a cylindrical bore 34 formed therein. Crankshaft 36 is pivotably mounted within the engine block in a conventional manner. Piston 38 slides with a cylindrical bore 34 and is connected to the crankshaft by connecting rod 40. A cylinder head 42 is affixed to the engine block to define an enclosed combustion chamber 44. Cylinder head 42 is provided with intake port 46 coupled to a carburetor 48 and selectively connected to the combustion chamber 44 by intake valve 50. Cylinder head 42 is also provided with an exhaust port 52 connected to muffler 54 and selectively connected to combustion chamber 44 by exhaust valve 56.

As illustrated in Figures 2 and 3, the cylinder axis of four-cycle engine 30 is generally upright when in normal use. Engine block 32 is provided with enclosed oil reservoir 58. The reservoir is relatively deep so that there is ample clearance between the crankshaft and the level of the oil during normal use. As illustrated in Figure 2, the engine may be rotated about the crankshaft axis plus or minus at angle β before the oil level would rise sufficiently to contact the crankshaft. Preferably, β is at least above 30° and most preferably at least 45° in order to avoid excessive interference between the crankshaft and the oil within the oil reservoir. As illustrated in a cross-sectional side elevation shown in Figure 3, the engine shown in its vertical orientation would typically be used in a line trimmer canted forward 20° to 30° . As illustrated, the engine can be tipped fore and aft plus or minus an angle α without the oil within the reservoir striking the crankshaft. Again, preferably the angle α is at least above 30° viewing the engine in side view

along the transverse axis orthogonal to the axes of the engine crankshaft 36 and the cylinder bore 34.

In order to lubricate the engine, connecting rod 40 is provided with a splasher portion 60 which dips 5 into the oil within the reservoir with each crankshaft revolution. The splasher 60 creates an oil mist which lubricates the internal moving parts within the engine block.

As illustrated in Figure 3, the crankshaft 36 10 is of a cantilever design similar to that commonly used by small two-cycle engines. The crankshaft is provided with an axial shaft member 62 having an output end 64 adapted to be coupled to the implement input member and input end 66 coupled to a counterweight 68. A crankpin 15 70 is affixed to counterweight 68 and is parallel to and radially offset from the axial shaft 62. Crankpin 70 pivotally cooperates with a series of roller bearings 72 mounted in connecting rod 40. The axial shaft 62 of crankshaft 36 is pivotably attached to the engine block 20 32 by a pair of conventional roller bearings 74 and 76. Intermediate roller bearings 74 and 76 is camshaft drive gear 78.

The camshaft drive and valve lifter mechanism 25 is best illustrated with reference to Figures 3 and 4. Drive gear 78 which is mounted upon the crankshaft drives cam gear 80 with is twice the diameter resulting in the camshaft rotating in one-half engine speed. Cam gear 80 is affixed to the camshaft assembly 82 which is journaled to engine block 32 and includes a rotary cam 30 lobe 84. In the embodiment illustrated, a single cam lobe is utilized for driving both the intake and exhaust valves, however, a conventional dual cam system could be utilized as well. Cam lobe 84 as illustrated in Figure

4, operates intake valve follower 86 and intake push rod 88 as well as exhaust valve follower 90 and exhaust push rod 92. Followers 86 and 90 are pivotably connected to the engine block by pivot pin 92. Push rods 88 and 92 extend between camshaft followers 86 and 90 and rocker arms 94 and 96 located within the cylinder head 42. Affixed to the cylinder head 42 is a valve cover 98 which defines therebetween enclosed valve chamber 100. A pair of push rod tubes 102 surround the intake and exhaust push rods 88 and 92 in a conventional manner in order to prevent the entry of dirt into the engine. In the embodiment of the invention illustrated, four-cycle engine 30 has a sealed valve chamber 100 which is isolated from the engine block and provided with its own lubricant. Preferably, valve chamber 100 is partially filled with a lightweight moly grease. Conventional valve stem seals, not shown, are provided in order to prevent escape of lubricant.

Engine 30 operates on a conventional four-cycle mode. Spark plug 104 is installed in a spark plug hole formed in the cylinder head so as to project into enclosed combustion chamber 44. The intake charge provided by carburetor 48 will preferably have an air fuel ratio which is slightly lean stoichiometric, i.e., having an air fuel ratio expressed in terms of stoichiometric ratio which is not less than 1.0. It is important to prevent the engine from being operated rich as to avoid a formation of excessive amounts of hydrocarbon (HC) and carbon monoxide (CO) emissions. Most preferably, the engine will operate during normal load conditions slightly lean of stoichiometric in order to minimize the formation of HC, CO and oxides of nitrogen (NO_x). Running slightly lean of stoichiometric air fuel ratio will enable excess oxygen to be present in the exhaust gas thereby fostering post-combustion

reduction of hydrocarbons within the muffler and exhaust port.

For use in a line trimmer of the type illustrated in Figure 1, adequate power output of a small lightweight four-cycle engine is achievable utilizing an engine with a displacement less than 80 cc. Preferably, engines for use in the present invention will have a displacement falling within the range of 20 and 60 cc. Engines of displacement larger than 80 cc. will result in excessive weight to be carried by an operator. Engines of smaller displacement will have inadequate power if operated in such a manner to maintain low emission levels.

In order to achieve high power output and relatively low exhaust emissions, four-cycle engine 30 is provided with a very compact combustion chamber 44 having a relatively low surface to volume ratio. In order to maximize volumetric efficiency and engine output for relatively small engine displacement, canted valves shown in Figure 2 are used resulting in what is commonly referred to as a hemispherical-type chamber. Intake and exhaust ports 46 and 52 are oriented in line and opposite one another resulting in a cross flow design capable of achieving very high horsepower relative to engine displacement compared to a typical four-cycle lawn mower engine having a flat head and a valve-in-block design.

A second engine embodiment 110 is illustrated in Figures 5 and 6. Engine 110 is very similar to engine 30 described with reference to Figures 2-4 except for the valve train and lubrication system design. Engine 110 is provided with a camshaft 112 having a pair of cam lobes, intake cam lobes 114 and exhaust cam lobes

116 affixed to the camshaft and at axially spaced apart orientation. Camshaft 112 is further provided with a cam gear 118 cooperating with a drive gear 119 affixed to the crankshaft as previously described with reference
5 to the first engine embodiment 30. Intake and exhaust followers 120 and 122 are slidably connected to the engine block and are perpendicular to the axis of the camshaft in a conventional manner. Intake and exhaust followers 120 and 122 reciprocally drive intake and
10 exhaust push rods 124 and 126.

Engine 110 also differs from engine 30 previously described in the area of cylinder head lubrication. Cylinder head 128 and valve cover 130 define therebetween an enclosed valve chamber 132.
15 Valve chamber 132 is coupled to oil reservoir 134 by intake and exhaust push rod guide tubes 136 and 138. Valve cover 130 is further provided with a porous breather 140 formed of a sponge-like or sintered metal material. As the piston reciprocates within the bore,
20 the pressure within the oil reservoir will fluctuate. When the pressure increases, mist laden air will be forced through the valve guide tubes into the valve chamber 132. When the piston rises, the pressure within the oil reservoir 134 will drop below atmospheric pressure causing air to be drawn into the engine
25 breather 140. The circulation of mist laden air between the engine oil reservoir and the valve chamber will supply lubrication to the valves and rocker arms. By forming the breather of a porous material, the escape
30 of oil and the entry of foreign debris will be substantially prohibited.

Figure 7-10 illustrate a third engine embodiment 150 having yet a third system for lubricating overhead valves. Engine 150 has an engine block with a

single cam and dual follower design generally similar to that of Figures 2 and 3 described previously. Cylinder head 152 is provided with a valve cover 154 to define enclosed valve chamber 156 therebetween. Valve chamber 5 156 is coupled to oil reservoir 158 within the engine block. In order to induce the mist laden air within the oil reservoir 158 to circulate through valve chamber 156, flow control means is provided for alternatively 10 selectively coupling the valve chamber to the oil reservoir via one of a pair of independent fluid passageways.

As illustrated in Figures 8 and 9, intake push rod tube 160 provides a first passageway connecting the oil reservoir to the valve chamber, while exhaust push 15 rod tube 162 provides a second independent passageway connecting the valve chamber 156 to the oil reservoir 158. As illustrated in Figure 8, port B connects push rod tube 162 to the cylindrical bore 166. Port B intersects the cylindrical bore at a location which is 20 swept by the skirt of piston 168 so that the port is alternatively opened and closed in response to piston movement. Camshaft 170 is pivotally mounted on a hollow tubular shaft 172. Camshaft 170 and support shaft 172 are each provided with a pair of ports A which are 25 selectively coupled and uncoupled once every engine revolution, i.e., twice every camshaft revolution. When the ports are aligned, the oil reservoir is fluidly coupled to the valve chamber via the intake push rod tube 160. When the ports are misaligned, the flow path 30 is blocked.

Figure 10 schematically illustrates the open and close relationship of the A and B ports relative to crankcase pressure. When the piston is down and the crankcase is pressurized, the A port is open allowing

5 mist laden air to flow through the passageway within camshaft support shaft 172 through the intake push rod tube 160 and into the valve chamber 156. When the piston rises, the crankcase pressure drops below atmospheric pressure. When the piston is raised, the A port is closed and the B port is opened enabling the pressurized air from valve chamber 156 to return to oil reservoir 158.

10 Of course, other means for inducing the circulation of misladen air from the oil reservoir to the valve chamber can be used to obtain the same function, such as check valves or alternative mechanically operated valve designs. Having a loop type flow path as opposed to a single bi-directional flow path, as in the case of the second engine embodiment 110, more dependable supply of oil can be delivered to the valve chamber.

20 It is believed that small lightweight four-cycle engines made in accordance with the present invention will be particularly suited to use with rotary line trimmers, as illustrated in Figure 1. Rotary line trimmers are typically directly driven. It is therefore desirable to have an engine with a torque peak in the 7000 to 9000 RPM range which is the range in which common line trimmers most efficiently cut. As illustrated in Figure 11, a small four-cycle engine of the present invention can be easily tuned to have a torque peak corresponding to the optimum cutting speed of a line trimmer head. This enables smaller horsepower engine to be utilized to achieve the same cutting performance as compared to a higher horse power two-cycle engine which is direct drive operated. Of course, a two-cycle engine speed can be matched to the optimum performance speed of the cutting head by using a gear

reduction, however, this unnecessarily adds cost, weight and complexity to a line trimmer.

Another advantage to the four-cycle engine for use in a line trimmer is illustrated with reference to Figures 12 and 13. Figure 12 plots the starter rope pull force versus engine revolutions. The force pulses occur every other revolution due to the four-cycle nature of the engine. A two-cycle engine as illustrated in Figure 13 has force pulses every revolution. It is therefore much easier to pull start a four-cycle engine to reach a specific starting RPM since approximately half of the work needs to be expended by the operator. Since every other revolution of a four-cycle engine constitutes a pumping loop where there is relatively little cylinder pressure, the operator pulling starter rope handle 174 (shown in Figure 1) is able to increase engine angular velocity during the pumping revolution so that proper starting speed and sufficient engine momentum can be more easily achieved. The pull starter mechanism utilized with the four-cycle engine is of a conventional design. Preferably, the pull starter will be located on the side of the engine closest to the handle in order to reduce the axial spacing between trimmer handle 24 and the starter rope handle 174, thereby minimizing the momentum exerted on the line trimmer during start up. A four-cycle engine is particularly advantageous in line trimmers where in the event the engine were to be shut off when the operator is carrying the trimmer, the operator can simply restart the engine by pulling the rope handle 174 with one hand and holding the trimmer handle 24 with the other. The reduced pull force makes it relatively easy to restart the engine without placing the trimmer on the ground or restraining the cutting head, as is frequently done with two-cycle line trimmers.

It should be understood, of course, that while the invention herein shown and described constitutes a preferred embodiment of the invention, it is not intended to illustrate all possible variations thereof. Alternative structures may be created by one of ordinary skill in the art without departing from the spirit and scope of the invention described in the following claims.

Throughout this specification and claims which follow, unless the context requires otherwise, the word "comprise", and variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated integer or group of integers or steps but not the exclusion of any other integer or group of integers.

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:-

1. A portable, operator-carried power tool having a frame and an operator-controlled implement supported by the frame at one end thereof, said tool having a four-cycle internal combustion engine having a displacement not greater than 80cc, being drivably connected to said implement and being attached to said frame.
2. A power tool as claimed in claim 1 in which the engine comprises:
 - an engine block having formed therein a single cylinder;
 - a piston slidably disposed in the cylinder;
 - a cylinder head assembly having an overhead air-fuel intake valve and an overhead combustion gas exhaust valve disposed therein;
 - a crankshaft rotatably mounted in the engine block and drivably connected to the implement;
 - a connecting rod connecting the piston to the crankshaft;
 - and
 - a reservoir for lubricating oil.
3. A power tool as claimed in claim 2 further comprising means connected drivingly to the crankshaft for displacing lubricating oil from the reservoir and creating an oil mist to lubricate the engine.
4. A power tool as claimed in claim 3, wherein the means for displacing lubricating oil is a splasher.

5. A power tool as claimed in claim 4, wherein the splasher is formed on an end of the connecting rod, said end being connected to the crankshaft.

6. A power tool as claimed in any one of claims 2 to 5, further comprising a hand grip portion of the frame to facilitate manoeuvres of the implement by the operator from a position corresponding to a normal vertical orientation of the cylinder.

7. A power tool as claimed in any one of claims 2 to 6, wherein the engine can be rotated at least 30 degrees about an axis orthogonal to that of the crankshaft and the piston and at least 45 degrees about an axis parallel to that of the crankshaft without interference between the lubricating oil and the crankshaft.

8. A power tool as claimed in any one of claims 2 to 7 in which said implement has a rotary driven input member to which is operatively coupled an output member of the engine.

9. A power tool as claimed in any one of claims 2 to 8 in which the engine includes a lightweight engine assembly having portions thereof forming the engine block and a cylinder head assembly, the engine block having defined therein a cylindrical bore, the cylinder head assembly having defined therein a spark plug hole and, in co-operation with the cylinder head assembly and the piston defining a combustion chamber.

10. A power tool as claimed in any one of claims 7 to 9 in which a cam is rotatably driven by the crankshaft, and the

crankshaft has an axial shaft with an output end adapted to be attached to the implement input member and an input end coupled to a parallel radially offset crankpin and a counterweight, the engine further having a bearing journal for rotatably supporting the crankshaft.

11. A power tool as claimed in any one of claims 2 to 10, in which the connecting rod further comprises a first end having a bearing for pivotally co-operating with the piston and a bearing assembly for pivotally co-operating with the crankshaft.

12. A power tool as claimed in claim 11, wherein the connecting rod bearings comprise roller bearings.

13. A power tool as claimed in any one of claims 2 to 12, wherein said oil reservoir is sufficiently deep so that the engine can be rotated at least 30° about a transverse axis orthogonal to the axis of the crankshaft and the cylinder without the oil within the oil reservoir rising above the level of the counterweight provided on the crankshaft.

14. A power tool as claimed in any one of claims 2 to 13, wherein one or more of the engine block, cylinder head assembly and piston is made of aluminum.

15. A power tool as claimed in any one of claims 2 to 14, having a throttle-controlled air-fuel mixture intake port and a combustion gas exhaust port disposed in a combustion chamber at opposed locations, whereby a combustible air-fuel mixture and combustion gas products transverse the combustion chamber in a

cross-flow fashion from the intake port to the exhaust port, the burning of the combustible air-fuel mixture being nearly stoichiometric throughout a range of throttle positions;

an overhead air-fuel intake valve and an overhead combustion gas exhaust valve respectively disposed in the intake port and the exhaust port;

a valve-operating cam drivably connected to the crankshaft, whereby the cam is driven at one-half crankshaft speed;

a valve train forming a driving connecting between the overhead air-fuel intake and the combustion gas exhaust valves and the cam;

the reservoir being disposed sufficiently remotely from the crankshaft so that the engine can be positioned in orientations that vary with respect to the normal, vertical orientation of the piston without interference between the lubricating oil and the crankshaft during ordinary operating manoeuvres of the power tool by an operator; and

passageways for conducting the oil mist from the reservoir to the overhead air-fuel intake valve and the overhead combustion gas exhaust valve.

16. A power tool as claimed in claim 15, wherein the driving connection between the overhead air-fuel intake and the combustion gas exhaust valves and the cam includes valve actuating rocker arms disposed in the cylinder head assembly and push rods disposed between the rocker arms and the cam.

17. A power tool as claimed in claim 15 or claim 16, wherein the combustion chamber has a generally hemispherical configuration, wherein the overhead air-fuel intake and the

combustion gas exhaust valves are outwardly canted with respect to each other to accommodate the hemispherical shape of the combustion chamber, and the air-fuel mixture intake port and the combustion gas exhaust port are generally in line and oriented opposed to each other to promote a cross-flow of gases from the former to the latter.

18. A power tool as claimed in any one of claims 2 to 17, further comprising a valve cover attached to the cylinder head assembly to define a valve chamber generally enclosing the overhead air-fuel intake valve and the overhead combustion gas exhaust valve.

19. A power tool as claimed in any one of claims 2 to 18 further comprising a head lubrication system including a first passageway connecting the oil reservoir to the valve chamber to induce circulation of the oil mist therebetween.

20. A power tool as claimed in claim 19 further comprising a second passageway connecting the oil reservoir to the valve chamber and valve means selectively opening and closing at least one of the passageways to induce the circulation of oil mist between the oil reservoir and the valve chamber.

21. A power tool as claimed in claim 20 in which the valve means selectively opens and closes both passageways to induce the circulation of oil mist.

22. A power tool as claimed in claim 19 further comprising a second passageway connecting the oil reservoir to the valve

chamber and means (A) opening and closing said passageways to induce the circulation of oil mist between the oil reservoir and the valve chamber.

23. A power tool as claimed in any one of claims 18 to 22, further comprising a breather co-operating with the engine oil reservoir and in communication with the valve chamber enabling air to exit and to enter the valve chamber thereby inducing the flow of oil mist from the oil reservoir to the valve chamber.

24. A power tool as claimed in any one of claims 18 to 23 in which the valve chamber is sealed and isolated from the oil reservoir and provided with an independent lubricant for the valves.

25. A power tool as claimed in any one of claims 15 to 24 in which the valve train operatively co-operates with the cam for sequentially activating the intake and exhaust valves at one-half engine speed.

26. A power tool as claimed in any one of claims 15 to 25, further comprising an induction system coupled to the intake port and including a throttle for regulating air flow and fuel metering means for maintaining an air fuel ratio at standard operating conditions, expressed in terms for stoichiometric ratio, which is not less than 1.0.

27. A power tool as claimed in any one of the preceding claims, wherein the displacement of the engine is between 20 and 60cc.

28. A power tool as claimed in any one of the preceding claims, wherein the implement is a rotary line trimmer head and the frame includes an elongate tubular boom with the engine attached to one end and the implement attached to the opposite end, and wherein the frame includes a handle disposed therebetween.

29. A portable operator-carried power tool having a frame to be carried by an operator, an implement co-operating with the frame and having a rotary driven input member and an internal combustion engine attached to the frame provided with an output member operatively coupled to the implement input member the engine including a lightweight engine assembly having portions thereof forming an engine block and a cylinder head assembly, the engine block having defined therein a cylindrical bore, the cylinder head assembly having defined therein a spark plug hole and having partially defined therein a combustion chamber, the engine further including a crankshaft, a piston and a connecting rod assembly the engine being a four-cycle engine comprising:

 a cam rotatably driven by the crankshaft, the crankshaft having an axial shaft with an output end adapted to be attached to the implement input member and an input end coupled to a parallel radially offset crankpin and a counterweight;

 the engine further having an enclosed oil reservoir which is partially filled with a quantity of oil, and the bearing journal for rotatably supporting the crankshaft;

 the cylindrical bore having a substantially upright orientation within the engine block;

 the piston reciprocally co-operating within the bore to provide an engine displacement not greater than 80cc;

 the connecting rod assembly including a first end having a

bearing for pivotally co-operating with the piston and a bearing assembly for pivotally co-operating with the crankshaft;

a splasher driven by the crankshaft to engage the oil within the enclosed oil reservoir in order to create an oil mist which lubricates the engine;

the cylinder head assembly defining a combustion chamber in co-operation with the cylinder bore and the piston, the cylinder head assembly having a spark plug and overhead intake and exhaust ports extending into the combustion chamber with an intake valve and an exhaust valve respectively co-operating therewith; and

a valve train operatively co-operating with the cam for sequentially activating the intake and exhaust valves at one-half engine speed.

30. A power tool as claimed in claim 29, wherein said intake and exhaust valves are outwardly canted relative to one another to form a generally hemispherically shaped combustion chamber and wherein said intake and exhaust ports are generally in line and oriented opposed to one another in a cross flow manner.

31. A power tool as claimed in claim 29 or claim 31, further comprising a head lubrication system including a first passageway connecting the oil reservoir to a valve chamber to provide the oil mist to lubricate the valve train.

32. A power tool as claimed in claim 31 further comprising a second passageway connecting the oil reservoir to the valve chamber and a valve selectively opening and closing at least one of the passageways to induce the circulation of oil mist between

the oil reservoir and the valve chamber.

33. A power tool as claimed in claim 32 in which the valve selectively opens and closes both passageways to induce the circulation of oil mist.

34. A power tool as claimed in claim 31 further comprising a second passageway connecting the oil reservoir to the valve chamber and means (A) opening and closing said passageways to induce the circulation of oil mist between the oil reservoir and the valve chamber.

35. A power tool as claimed in any one of claims 31 to 34, further comprising a breather co-operating with the engine oil reservoir and in communication with the valve chamber enabling air to exit and to enter the valve chamber thereby inducing the flow of oil mist from the oil reservoir to the valve chamber.

36. A power tool as claimed in any one of claims 29 to 35, further comprising a valve cover attached to the cylinder head assembly to define a valve chamber therebetween at least partially enclosing the valve train, said valve chamber being sealed and isolated from the oil reservoir and provided with an independent lubricant for the valves.

37. A power tool as claimed in any one of claims 29 to 36, further comprising an induction system coupled to the intake port and including a throttle for regulating air flow and fuel metering means for maintaining an air fuel ratio at standard operating conditions, expressed in terms for stoichiometric

ratio, which is not less than 1.0.

38. A power tool as claimed in any one of claims 29 to 37, wherein said engine displacement is between 20 and 60cc.

39. A power tool as claimed in any one of claims 29 to 38, wherein said oil reservoir is sufficiently deep so that the engine can be rotated at least 30° about a transverse axis orthogonal to the axis of the crankshaft and the cylindrical bore without the oil within the oil reservoir rising above the level of the crankshaft counterweight.

40. A power tool as claimed in any one of claims 29 to 39, wherein said implement comprises a rotary line trimmer head and said frame further comprises an elongated tubular boom with the engine attached to one end and the line trimmer head attached to the opposite end with a handle oriented therebetween.

41. A power tool as claimed in any one of claims 29 to 40, wherein one or more of the engine block, cylinder head assembly and piston are made of aluminum.

42. A power tool as claimed in any one of claims 29 to 41, wherein the connecting rod bearings comprise roller bearings.

- 25 -

43. A power tool as claimed in any one of claims 29 top 42, wherein the splasher is formed on the second end of the connecting rod.

DATED this 31st day of August, 1998.

RYOBI OUTDOOR PRODUCTS INC.

By his Patent Attorneys:

DAVIES COLLISON CAVE

A B S T R A C T

A portable, operator-carried power tool having a frame and an operator-controlled implement supported by the frame at one end thereof, said tool having a four-cycle internal combustion engine having a displacement not greater than 80cc, being drivably connected to said implement and being attached to said frame.
